

Summary:

- **Step1:** Reading and Understanding Data. Read and analyses the data.
- **Step2:** Data Cleaning: We dropped the variables that had high percentage of NULL values in them. This step also included imputing the missing values as and where required with median values in case of numerical variables and creation of new classification variables in case of categorical variables. The outliers were identified and removed.
- **Step3:** Data Analysis Then we started with the Exploratory Data Analysis of the data set to get a feel of how the data is oriented.
- **Step4:** Creating Dummy Variables, we went on with creating dummy data for the categorical variables.
- **Step5:** Test Train Split: The next step was to divide the data set into test and train sections with a proportion of 70-30% values.
- **Step6:** Feature Rescaling We used the Min Max Scaling to scale the original numerical variables. Then using the stats model we created our initial model, which would give us a complete statistical view of all the parameters of our model.
- **Step7:** Feature selection using RFE: Using the Recursive Feature Elimination we went ahead and selected the 15 top important features. Using the statistics generated, we recursively tried looking at the P-values in order to select the most significant values that should be present and dropped the insignificant values.
- Finally, we arrived at the 11 most significant variables. The VIF's for these variables were also found to be good. We then created the data frame having the converted probability values and we had an initial assumption that a probability value of more than 0.5 means 1 else 0. Based on the above assumption, we derived the Confusion Metrics and calculated the overall Accuracy of the model. We also calculated the 'Sensitivity' and the 'Specificity' matrices to understand how reliable the model is.
- **Step8:** Plotting the ROC Curve We then tried plotting the ROC curve for the features and the curve came out be pretty decent with an area coverage of 88% which further solidified the of the model.
- **Step9:** Finding the Optimal Cutoff Point Then we plotted the probability graph for the 'Accuracy', 'Sensitivity', and 'Specificity' for different probability values. The intersecting point of the graphs was considered as the optimal probability cutoff point. The cutoff point was found out to be 0.35 Based on the new value we could observe that close to 80% values were rightly predicted by the model. We could also observe the new values of the 'accuracy=81%', 'sensitivity=80%', 'specificity=81%'. Also calculated the lead score and figured that the final predicted variables approximately gave a target lead prediction of 80%.
